(54) GOLF CLUB HEAD

(57) A golf club head comprising a hitting face for golf balls, said hitting face being formed at least partially by a metallic material, said metallic material satisfying the following relation:

$$y \geq 0.006x + 60$$

wherein

x is Young's modulus(unit: kgf/mm²), and
y is tensile strength(unit: kgf/mm²).

The metallic material is preferably an amorphous metal.

Description

TECHNICAL FIELDS

5 [0001] The present invention relates to a golf club head for hitting golf balls.

BACKGROUND OF THE INVENTION

10 [0002] Wood type golf club heads for which persimmon has been mainly used have recently changed to be made of metallic materials such as carbon steel, stainless steel, duralumin, titanium or the like. Such golf club heads can be provided with a larger head volume and a wider hitting face area as well as a larger moment of inertia for obtaining a more stable direction of the golf ball. In addition, a larger sweet area of head is obtainable so as to reduce the lowering of the resiliency of the ball on a missed shot. Moreover, a larger sized golf club head brings about better stability on addressing the ball as well as permitting a longer shaft to be fitted to obtain an increased carry.

15 [0003] By the way, the present applicant has obtained the Japanese Patent No.2130519 (No.33071 in the Japan Patent Official Gazette of 1993) for a golf club head which provides increased carry by means of increasing to the full the resiliency performance between the head and the golf ball. In said patent, a theory that by means of approaching a frequency indicating the primary minimum of the mechanical impedance of the head of the golf club (hereinafter referred to in short as "a primary frequency of the mechanical impedance of head",) to the frequency indicating the primary minimum of the mechanical impedance of the golf ball (hereinafter referred simply to as "the primary frequency of the impedance of ball" which proves to be about 600 Hz to about 1600Hz.), the initial speed of the impacted ball is raised to the full (hereinafter may be referred to as "the impedance matching theory") has been disclosed.

20 [0004] "Mechanical impedance" is defined as the ratio of the magnitude of a force acting on a point to the responding velocity of another point when said force acts. Namely, when the force applied to an object from outside and the responding velocity are expressed by F and V respectively, the mechanical impedance (Z) is defined as $Z = F/V$.

25 [0005] In order to reduce the primary frequency of the impedance of a head, it is effective to reduce the rigidity of the hitting face of the head. For example, a larger area of the hitting face, a thinner hitting face, an application of a low Young's modulus material to the hitting face or the like can be cited.

30 [0006] In particular, it is empirically known that, the application of a low Young's modulus metallic material to the hitting face of the head renders the feeling (hitting feeling) soft on hitting a golf ball and, favourable to say, even a missed hit which transmits only a small shock to the hands.

35 [0007] A metallic material with a small tensile strength, even with a low Young's modulus, however, makes it hard to provide sufficient strength sufficient to endure the shock on impact. Moreover, to enlarge the thickness of the hitting face to provide the required strength of the latter resulted only in little effect of reducing the rigidity of the said face, which confirmed an existence of a limit to reducing the primary frequency of the impedance of head.

[0008] Also even with a low Young's modulus, a metallic material with a small surface hardness suffers from such problems as the tendency for early wear, easy scratching or the like of the surface of the hitting face due to the friction with the ball on impact and sand caught between the hitting face and the ball on impact.

40 DISCLOSURE OF THE INVENTION

[0009] The object of the present invention is to provide a golf club head capable of increasing the carry on the basis of the above mentioned "impedance matching theory" by reduction in the rigidity of the hitting face but providing a strength durable to the shock on impact.

45 [0010] Accordingly the present invention provides a golf club head comprising a hitting face for a golf ball, said hitting face being formed at least partially by a metallic material, said metallic material satisfying the following relation:

$$y \geq 0.006x + 60$$

50 wherein, x is Young's modulus(unit: kgf/mm²), and y is the tensile strength (unit:kgf/mm²).

[0011] For said metallic material an amorphous metal may be used and in particular an amorphous alloy of zirconium base.

55 [0012] Moreover, the object of the inventions according to claims 5 to 8 consists in that on the basis of reduction in rigidity of the hitting face with a sufficient hardness, to prevent wear and scratching due to friction with the golf balls on impact and the intervention of sand etc., is to provide a golf club head capable of presenting a soft hitting feeling as well as a longer carry on the basis of the impedance matching theory. Accordingly the present invention also provides a golf club head comprising a hitting face for golf balls, the surface of said hitting face being formed by at least partially a metallic material, said metallic material satisfying the relation:

$$z \geq (x/60) + 200$$

wherein, x is Young's modulus(unit: kgf/mm^2), and z is Vickers hardness(unit: HV).

[0013] Said metallic material is preferably an amorphous metal and in particular an amorphous alloy of zirconium base.

BRIEF DESCRIPTION OF DRAWINGS

[0014]

Fig.1 is a front view of an embodiment of a wood type golf club head according to the invention;
 Fig.2 is a side view of Fig. 1;
 Fig.3 is a cross sectional view of Fig.2;
 Figs.4(A) and 4(B) are cross sectional views of other embodiments of a golf club head;
 Fig.5 is a cross sectional view of head showing another embodiment;
 Fig.6 is a front view showing an embodiment of an iron type golf club head;
 Fig.7 is a cross sectional view thereof;

 Fig.9 is a graph showing the relation between Young's modulus and Vickers hardness.

THE BEST EMBODIMENT FOR REALISING THE INVENTION

[0015] An embodiment of the present invention will now be explained according to drawings. Fig.1, Fig.2 and Fig.3 illustrate a golf club head according to the present invention in the form of a hollow wood type golf club head formed of a metallic material. In this example, the head comprises a head body 1 and a face plate 2 arranged at the front of the head body 1. It is preferable that the golf club head is provided with a head volume of, for example, about 80 cm^3 to about 360 cm^3 , and more preferably of about 230 cm^3 to about 360 cm^3 .

[0016] The head body 1 is provided with a face mounting part 1a constituting a periphery of a hitting face 6 for golf balls and being to fixed thereon the face plate 2, a sole 7 adjoining the face mounting part 1a, a crown part 8 and a side part 9. The face mounting part 1a is shown in the form which is formed to provide an opening 3 bored through into the head and provided with a stepped down zone 3a for attaching the face plate 2 as shown in Fig.3.

[0017] Moreover, the face plate 2, which comprises the main part of the hitting face 6 in the present example, is disposed into said opening 3 and retained by a joining means such as welding, caulking and adhesive so as to constitute the hitting face 6 in cooperation with the face mounting part 1a.

[0018] The face mounting part 1a may also be formed in the form of an opening 3 without the stepped down zone 3a as shown in Fig.4(A) and also as shown in Fig.4(B) in the form of a tapered concave zone 4 which widens towards the inside of the head to support the back of the face plate 2 as shown. In this case, it is preferable for the face plate 2 also to be made with substantially the same tapered form.

[0019] In addition, it was discovered and proved in various experiments made by the inventors that it is preferable that part of the hitting face 6 is formed by a metallic material satisfying the following relation:

$$y \geq 0.006x + 60$$

wherein

x is Young's modulus(unit: kgf/mm^2), and
 y is tensile strength (unit: kgf/mm^2).

[0020] The present embodiment has a face plate 2 formed by such a metallic material as part of the hitting face 6. Consequently, part of the hitting face 6 (in the present example, the face plate 2 comprising the main portion of the hitting face 6) has a low Young's modulus low and a tensile strength to give durability to shock impact. Accordingly, the golf club head permits the reduction of the primary frequency of the impedance of head and this increases the carry of the golf ball according to said impedance matching theory or to provide a soft feeling of hitting by reducing the shock on impact.

[0021] In addition, the golf club head by its Young's modulus and lighter head by allows smaller thickness to be used for the hitting face 6 or the face plate 2. Furthermore, the smaller the thickness of the face plate 2 becomes, the more the spring constant of the head is reduced, resulting in obtaining a still more reduced primary frequency of the impedance of the head.

[0022] Moreover, in the present example, the face plate 2 is shown as having nearly uniform thickness. The thickness of the face plate 2 is preferably, for example, about 1 mm to about 4 mm, and more preferably to be about 1 mm to about 3 mm. If the thickness of the face plate 2 is less than 1 mm then it tends to have a reduced strength and on the contrary if the eventual thickness is more than 4 mm then it tends to have less effect in reduction of the primary frequency of said impedance of the head and the weight thereof.

[0023] By the way, the primary frequency of the impedance of a golf ball ranges from about 600 Hz to about 1600 Hz, and that of an ordinary two-piece ball ranges from about 1000 Hz to about 1200 Hz. In contrast therewith, the primary frequencies of the impedance of a wood type head formed of conventional stainless steel and of that made of titanium are about 1800 Hz to about 2500 Hz and about 1400 Hz to about 2000 Hz respectively.

[0024] A golf club head according to the present embodiment permits a primary frequency of the impedance of the head less than that of a conventional head and it approximates to or coincides with the primary frequency of the impedance of the golf ball.

[0025] For example, the present embodiment has a primary frequency of the impedance of the head which is less than 1300 Hz. This is a value substantially coincident with that of a two piece ball. Consequently, the golf club head of the present embodiment permits an increase in the initial velocity of a hit ball on impact to the full, which results in increasing the carry.

[0026] Moreover, it is preferable that at least part of the hitting face 6 be formed by a metallic material satisfying the following relation:

$$y \geq 0.006x + 63$$

and more preferably of a metallic material satisfying the following relation:

$$y \geq 0.006x + 100$$

wherein the definition of x and y is as shown above.

[0027] By the way, if the metallic material of the face plate 2, for example, is such that $y < 0.006x + 60$, the balance between tensile strength and Young's modulus becomes worse and it becomes hard to reduce the rigidity of the hitting face and to maintain the strength durable to the shock on impact.

[0028] Moreover, in the present embodiment, the tensile strength of the metallic material of the face plate 2 is preferable to be maintained in such a degree as not increasing the thickness of the face plate 2 remarkably, namely it is preferable to be kept at not less than, for example, 80 kgf/mm², preferably not less than 105 kgf/mm² and more preferably not less than 130 kgf/mm². By the way, the upper limit of the tensile strength may be stipulated to be not more than 400 kgf/mm² in any combination with either of above lower limits in consideration of production problems.

[0029] Moreover, in the present embodiment the Young's modulus of the metallic material of the face plate 2 is preferred to be not less than, for example, 3000 kgf/mm² and preferably not less than 5000 kgf/mm². However, because a too high Young's modulus is apt to raise the rigidity of the hitting face 6, so its upper limit is preferred to be not more than 25000 kgf/mm² and preferably not more than 20000 kgf/mm² and more preferably not more than 16000 kgf/mm² and further preferably not more than 12000 kgf/mm² and more further preferably not more than 10000 kgf/mm² in any combination with either of the lower limits.

[0030] While these embodiments were based on lowering the rigidity of the hitting face which maintain the strength durable to shock on impact, a description of such an embodiment to permit prevention of the surface of the hitting face being worn or scratched caused by the friction with the ball on impact or by sand caught between the hitting face and the ball now follows.

[0031] As for the present embodiment also, it is applicable to the golf club head in the form as shown in Figs. 1 to 3 or in Figs. 4 (A), (B). Thus the inventors have found that it is preferable to use a metallic material as the part of the surface of the hitting face satisfying the relation:

$$z \geq (x/60) + 200$$

wherein x is Young's modulus (unit: kgf/mm²), and z is Vickers hardness (unit: kgf/mm²).

[0032] For example, the face plate 2 is formed by a metallic material which satisfies the above relation $\{ z \geq (x/60) + 200 \}$. By the way, the present example is arranged so that the surface of the face plate 2 is exposed without being provided with any additional surface layer of other metal, resin, wood or the like.

[0033] Moreover, the Vickers hardness of the metallic material is that obtained from the relationship between the test load when the testing surface was dented with an indenter which was a regular square pyramid of diamond with a face angle of 136 degree and along with the dent surface area, as defined in Japanese-Industrial-Standard (JIS) or the like. The present invention stipulates the testing load as 30 kgf.

[0034] In the present embodiment, the face plate 2 has a high Vickers hardness so as to prevent the hitting face 6 from wear and scratching caused by friction with golf balls and sand caught within. Moreover, the metallic material of the face plate 2, which possesses the above stated relation of Young's modulus x with Vickers hardness z , allows the Young's modulus to be low with a high Vickers hardness.

[0035] Accordingly, the golf club head of the present embodiment can reduce the primary frequency of the impedance of head, permitting an increased carry of the ball according to the impedance matching theory. In addition, part of the surface of the hitting face, which suffers from a reduced shock on impact because of the lower Young's modulus, provides a softer hitting feel.

[0036] By the way, if the face plate 2 is a metallic material obeying $z < (x/60) + 200$, the simultaneous satisfaction of such three performances as softer hitting feeling, increase in carry and durability of hitting face 6 prove to be unobtainable.

[0037] In addition, because the face plate 2 provides a high Vickers hardness with a low Young's modulus, a reduction in the thickness of the hitting face 6 (face plate 2) is also possible. Accordingly, a lighter head may be produced and the spring constant of the head is increased corresponding to the reduction in the thickness of the face plate 2, a synergetic effect permitting further reduction of the primary frequency of the impedance of the head.

[0038] Herein, the Vickers hardness of the face plate 2 is preferably not less than 250 HV, more preferably not less than 300 HV, more preferably not less than 370 HV, or further preferably not less than 400 HV and so a very excellent injury or damage resistance is obtained. Moreover the upper limit may be stipulated as not more than 1000 HV from the view point of production problems or the like, also in a combination with either of said lower limits. The latter permits to obtain a more suitable protection of the hitting face from injury or damage.

[0039] In addition, it is preferable that at least part of the surface of the hitting face 6 is formed by a metallic material satisfying the relation:

$$z \geq (x/60) + 250$$

wherein the definition of x and z is as shown above.

[0040] In the present embodiment too, the Young's modulus of the face plate 2 is preferable to be, for example, not less than 3000 kgf/mm² and preferably not less than 5000 kgf/mm² to obtain the required rigidity. However, because a too high Young's modulus is apt to render the rigidity of the hitting face 6 higher, its upper limit is desired to be not more than 25000 kgf/mm² and preferably not more than 20000 kgf/mm² and more preferably not more than 16000 kgf/mm² and further preferably not more than 12000 kgf/mm², more further preferably not more than 10000 kgf/mm² in combination with either of said lower limits.

[0041] While said two embodiments were described, for metallic material comprising a face plate 2, it is preferable to use an amorphous metal. By amorphous metal is meant a metal whose atomic arrangement is not regular over a wide range. At present it is made mainly in such a manner that a fused alloy obtained by melting various alloy elements is rapidly cooled to solidify so that no crystal nucleus is produced and grown. In the present embodiment, an amorphous metal whose amorphous ratio that is the degree of amorphousness, that is to say, the ratio of the volume v_1 of the amorphous phase to the total volume v , (v_1/v) is over 50% is preferably used.

[0042] The amorphous metal consists of a composition expressed by a general formula: $M_a X_b$ (wherein "a" and "b" are $65 \leq a \leq 100$ and $0 \leq b \leq 35$ at atomic %).

[0043] Herein, M consists of metallic elements of more than one kind selected from Zr, V, Cr, Mn, Fe, Co, Ni, Cu, Ti, Mo, W, Ca, Li, Mg, Si, Al, Pd, Be, and X consists of metallic elements of more than one kind selected from Y, La, Ce, Sm, Md, Hf, Nb, Ta. And preferably, above "a", b are preferable to be $99 \leq a \leq 100$ and $0 \leq b \leq 1$ at atomic % respectively.

[0044] Because such amorphous metals, which may be provided simultaneously with a high tensile strength, a high Vickers hardness and a low Young's modulus, prove to be metallic materials particularly suitable for the golf club head of the present invention.

[0045] For said amorphous metal, amorphous alloys of zirconium base are more preferably applicable. The zirconium base amorphous metals are provided with a higher tensile strength as well as a lower Young's modulus. In addition, a relatively lower cooling velocity is applicable in production, accordingly, they are practical and preferable also from the view point that they allow by casting molten metal in a mould and cooling the manufacture of bulk or plate form products with relative ease.

[0046] The amorphous zirconium base alloys consist of a composition as shown by a general formula:

(wherein c, d and e are $20 \leq c \leq 80$, $20 \leq d \leq 80$ and $0 \leq e \leq 35$ atomic % respectively).

[0047] Here, Zr is zirconium, M is a metallic element of more than one kind selected from V, Cr, Mn, Fe, Co, Ni, Cu, Ti, Mo, W, Ca, Li, Mg, Si, Al, Pd, Be; and X consists of metallic elements more than one kind, selected from Y, La, Ce,

Sm, Md, Hf, Nb, Ta.

[0048] In addition, said c, d and e are preferably $35 \leq c \leq 75$, $25 \leq d \leq 65$ and $0 \leq e \leq 30$ respectively, more preferably to be $35 \leq c \leq 75$, $25 \leq d \leq 65$ and $0 \leq e \leq 1$ at atomic %, and further preferably to be $50 \leq c \leq 75$, $25 \leq d \leq 50$, $0 \leq e \leq 1$ at atomic % respectively. Moreover, said M is particularly preferable to be Al, Cu, Ni. Said X is preferable to be Hf. In particular, as such a zirconium base amorphous alloy, for example,

is preferable. (herein, shall be $d1+d2+d3=d$ and $c+d+e=100$).

[0049] The amorphous metal preferably has an amorphous ratio as mentioned above of not less than 75%, more preferably not less than 80% and further preferably not less than 90%. For example, such an amorphous ratio can be identified by means of observing under an optical microscope to determine the area of the amorphous portion after a mirror polishing followed by an etching treatment of a cut section of a sample of metallic material. The amorphous ratio can be adjusted by modifying the alloy composition of amorphous metal, the cooling temperature of cooling fused alloy for producing the amorphous metal as well as the oxygen concentration of the ambient gases and so on. Above all, the more said cooling velocity is raised and the more the oxygen concentration of the ambient gases is reduced, the more the amorphous ratio can be raised.

[0050] By the way, as for the metallic material of the face plate 2, any kind of metallic material such as any alloy or elemental metal other than amorphous metals, so long as it satisfies the relation between said Young's modulus and tensile strength or that between Young's modulus and Vickers hardness, may be applied, without being limited to the illustrated amorphous alloys.

[0051] In connection with the present embodiment, various methods permit design changes. For example, the face plate 2 may be constructed a thicker central part with a periphery part whose thickness reduces gradually outwardly. In this case, it is possible to obtain the smaller primary frequency of the impedance of the head without reducing the strength of the face plate 2. On the contrary, the face plate 2 may be constructed with a thinner central part with a periphery part whose thickness gradually increases outwardly. This case is preferable because the strength of the joint portion of the face plate 2 with the face mounting part 1a is increased.

[0052] Moreover, the head body 1 may be formed of conventional metallic materials such as titanium, titanium alloys, stainless steel or the like for example.

[0053] And also, as shown in Fig.5, the hitting face 6, the sole 7, the crown part 8 and the side part 9 constituting the head as a whole may be formed by a metallic material satisfying the following relation:

$$y \geq 0.006x + 60$$

wherein the definition of x and y is as shown above, or may be formed by a metallic material satisfying the following relation:

$$z \geq (x/60) + 200$$

wherein the definition of x and z is as shown above. In these case, further improved shock endurance and hitting feeling are obtained, resulting in a further reduction in the primary frequency of the impedance of the head.

[0054] In Figs.6 and 7, as another embodiment of the present invention, which is an iron type club head made of metal. In this example, the golf club head comprises a head body 101 and an insert plate 102 to provide the hitting face fitted on the hitting side face 104 of the head body 101. The insert plate 102 comprises the main part of the hitting face 104 to hit the golf ball chiefly on its surface. The insert plate 102 is shown formed substantially uniform in thickness as well as fitted in a fitting hollow formed on the side of the hitting face 104 and fixed by adhesion, welding, caulking, a press fit etc. Consequently, in this example, the back as a whole of the insert plate 102 for the hitting face comes into contact with or sticks to the head body 101, which results in an improvement of the durability of the hitting face 104.

[0055] Moreover, by means of applying for the insert plate 102 for the hitting face, for example, metallic material satisfying the following relation:

$$y \geq 0.006x + 60$$

wherein the definition of x and y is as shown above, or a metallic material satisfying the following relation:

$$z \geq (x/60) + 200$$

wherein the definition of x and z is as shown above, an effect similar to the above mentioned can be obtained.

[0056] While several embodiments have been described, although the present invention is preferable for wood type and iron type heads, it is also available for a putter type head.

[0057] In addition, in all embodiments above stated, the face plate 2 as well as the insert plate 102 for the hitting face may be formed by a metallic material simultaneously satisfying the following relations:

$$y \geq 0.006x + 60$$

$$z \geq (x/60) + 200$$

wherein the definition x, y and z is as shown above.

[0058] In this case, according to the impedance matching theory, such a further preferable golf club head is produced as possessing a strength durable to the shock on impact and a face with a very high durability resistant to injury or damage, simultaneously with an improvement in the carry of the ball.

WORKING EXAMPLE

(First Working example)

[0059] Wood type golf heads were produced (examples 1 to 6) with zirconium base amorphous alloys with variously varied alloy elements (Zr-Al-Cu-Ni-Hf, or Zr-Al-Cu-Ni) being applied to part of the hitting face. These golf club heads were used to investigate head speed, ball speed after hitting by the golf club head, resilience coefficient, carry (hitting distance from the hitting point to the first dropping point of the golf ball), total hitting distance, primary minimum frequency of the mechanical impedance of head and hitting feeling. The results were reported in Table 1. On the other hand, for comparison, references 1 and 2 were given wherein wood type hollow heads made of titanium and stainless steel were prepared for comparing several performances. The head speed, the ball speed, the resilience coefficient, the carry and the total hitting distance were determined by the hitting test by a golf swing robot. For measuring the primary minimum frequency of the mechanical impedance of the head an exciting measuring method was used with a vibration exciter, an acceleration pickup, a power unit, and a dynamic signal analyser as those utilised in said Japanese patent above. Moreover, the hitting feeling was evaluated by 20 golfers who actually hit and gave a score in 5 steps of 1 to 5 points of sensuous evaluation on the basis of less shock, (whether or not being obtained a soft hitting feeling) for obtaining its mean value.

[0060] As is clear from Table 1, while the primary minimum frequencies of mechanical impedance of the golf club heads of references 1 and 2 were 1450 Hz and 1980 Hz respectively, in examples of the invention, all the frequencies were held below 1290 Hz. Accordingly, golf club heads of all examples of the invention obtained primary minimum frequencies of the mechanical impedance of heads less than those of conventional heads and it was confirmed that they approximated to the primary minimum frequency of the mechanical impedance of a two piece ball (about 1000 Hz to about 1200 Hz). By the way, illustrated tensile strengths of metallic materials applied to the face plate were below 200 kgf/mm².

[0061] Moreover it is clear that resilience coefficient, carry, total hitting distance were all superior to those of references 1 and 2. In addition as for hitting feeling also, examples 1 to 6 were superior to references 1 and 2.

[0062] In these examples, the thickness of the face plate (amorphous metal part) was set smaller with increasing tensile strength. It is considered that this decrease in thickness further lowers the spring constant as regards the hitting face, which resulted in an increase in restitution coefficient, carry, and total hitting distance and an improvement in hitting feeling.

[0063] Moreover, Fig.8 shows the relation between Young's modulus x and tensile strength y. For metallic materials used for face plates of above mentioned examples 1 to 6 and references 1 and 2. Equally for data of duralumin, magnesium alloys, and super high tensile strength steels are shown.

[0064] In Fig. 8, straight lines 10, 11 and 12 are graphs showing $y=0.006x+60$, $y=0.006x+63$, and $y=0.006x+100$ respectively. Herein, a range satisfying, $y \geq 0.006x+60$ is indicated by oblique lines.

[0065] It is clear that while metallic materials used in the examples satisfy $y \geq 0.006x+60$, with materials used in references and with duralumin, magnesium alloy, super high tensile strength steels etc., $y < 0.006x+60$ is satisfied.

(Second Working Example)

[0066] Next, as another working example of the present invention, the relation between Young's modulus and Vickers hardness was investigated. Heads of iron type similar to what was shown in Figs.6 and 7 (examples 7 to 9) and of wood type similar to what was shown in Figs. 1 to 3 (examples 10 to 12) were produced. Moreover, iron type heads (refer-

ences 4 to 6) and wood type ones (references 7 to 9) whose insert plates for hitting face and face plates were made of stainless steel, titanium, or duralumin were produced. And as for these heads, tests were made chiefly in connection with the injury resistance of the surface of the hitting face and the softness of hitting feeling.

[0067] The injury resistance of the surface of the hitting face was determined in such a manner that a golf ball placed on the ground was hit by a golf swing robot so as to let between the contact faces a small amount of sand and then examining the amount of injury on the surface of the hitting face. On the other hand, the softness of hitting feeling was evaluated by 20 golfers to provide a mean value. The measuring load for the Vickers hardness was 30 kgf. Results of the tests are shown in Tables 2 and 3.

[0068] As is clear from Tables 2 and 3, for club heads of all examples, the surface of the hitting face was too hard to be injured (little injury or very little injury) and presented a soft hitting feeling (good or very good). And, at least either of performances of the injury of the hitting face and the soft feeling resulted as very good.

[0069] Moreover, example 7 gave a Vickers hardness similar to that of references 3, 4 (similar injury resistance) but its Young's modulus was very much lowered. Accordingly it can be seen that the golf club head of this example permitted an increase in carry and provided a soft hitting feeling on the one hand. Also it suffered little from injury from sand and pebbles on the other hand, so presenting an excellent wear resistance.

[0070] Fig.9 shows a relation between Young's modulus x and Vickers hardness z of metallic materials. The data of said metallic materials of face plates of examples 7 to 9 and references 3 to 8 and also of magnesium and super high tensile strength steels being plotted.

[0071] In said figure, straight lines 16 and 17 indicate $z=(x/60)+200$ and $z=(x/60)+250$ respectively. Moreover a range satisfying a relation $z \geq (x/60)+200$ is shown by oblique lines. As clear from said figure, examples 7 to 12 satisfy the relation $z \geq (x/60)+200$.

[0072] As described above, the golf club head according to the claim 1 permits part of the hitting face to be provided with a lower rigidity with tensile strength to be durable to shock on impact being maintained. Accordingly, a golf club head with a smaller primary minimum frequency of mechanical impedance of the head than that of a conventional golf club head is produced. For example, the value of the primary minimum frequency of the mechanical impedance of the golf club head may approach that of a golf ball. Consequently, a longer carry as well as a softer hitting feeling may be obtained. Moreover, for the golf club head, the thickness of its hitting face may be reduced and further reduction in weight may be attempted. When the thickness of the hitting face was reduced, by an amount corresponding thereto the spring constant of the hitting face is reduced and moreover the primary minimum frequency of the mechanical impedance may be reduced.

[0073] Also for the golf club head according to claim 2, for a metallic material suitable to said hitting face an amorphous metal is applied, which allows the obtaining with ease of a compromise between a high tensile strength and a low Young's modulus.

[0074] For the golf club head according to the claim 3 or 4, an amorphous alloy of zirconium base is applied, which permits its simple production and in addition the compromise between a higher tensile strength and a lower Young's modulus.

[0075] For the golf club head according to the claim 5, at least part of the surface of the hitting face can be made so as to keep its low rigidity with its surface hardness durable to friction and sand intervention on impact being maintained. Accordingly, a primary minimum frequency of the mechanical impedance less than that of the conventional golf club is available with the durability and injury resistance of the head being maintained. For example, the primary minimum frequency of the mechanical impedance of a golf club head may be further approximated to that of golf ball. Accordingly, an increased carry as well as a softer hitting feeling at hitting is obtained. Moreover, a smaller thickness of the hitting face of the golf club head may be obtained, which means a further reduced weight being obtainable. In addition, a reduction in the thickness of the hitting face induces a reduction in the spring constant by its corresponding amount and in addition permits further reduction of the primary minimum frequency of the mechanical impedance.

[0076] With the golf club head according to the claim 6, the application of an amorphous metal as the metallic material suitable for the said hitting face permits the achievement with ease of a compromise of a high tensile strength with a low Young's modulus.

[0077] Moreover, the golf club head according to claim 7 or 8, for which is applied an amorphous alloy of zirconium base, may be made in a simpler manner and in addition, a compatibility of a higher tensile strength with a lower Young's modulus may be attainable.

Claims

1. A golf club head comprising a hitting face for golf balls, said hitting face being formed at least partially by a metallic material, said metallic material satisfying the following relation:

$$y \geq 0.006x + 60$$

wherein

x is Young's modulus(unit: kgf/mm²), and
y is tensile strength (unit: kgf/mm²).

2. A golf club head according to the claim 1, wherein said metallic material is an amorphous metal.
3. A golf club head according to the claim 1, wherein said metallic material is an amorphous alloy of zirconium base.
4. A golf club head according to the claim 1, wherein said metallic material is an amorphous alloy comprising Zr, Al, Cu, Ni, Hf or said amorphous alloy comprising Zr, Al, Cu, Ni.
5. A golf club head comprising a hitting face for golf balls, the surface of said hitting face being formed at least partially by a metallic material, said metallic material satisfying the following relation:

$$z \geq (x/60) + 200$$

wherein

x is Young's modulus(unit: kgf/mm²), and
z is Vickers hardness(unit: HV).

6. A golf club head according to the claim 5, wherein said metallic material is an amorphous metal.
7. A golf club head according to the claim 5, wherein said metallic material is an amorphous alloy of zirconium base.
8. A golf club head according to the claim 5, wherein said metallic material is an amorphous alloy comprising Zr, Al, Cu, Ni, Hf or said amorphous alloy comprising Zr, Al, Cu, Ni.
